Holt Theoretical And Experimental Probability
The theoretical probability is 8.3% and the experimental probability is 4%. Although the experimental probability is slightly lower, this is not a significant difference. In most experiments, the theoretical probability and experimental probability will not be equal; however, they should be relatively close.

Theoretical probability is a probability that is expected, for example when I flip a coin 100 times I expect tails to come up 50 times and heads to come up 50 times. The theoretical probability is 0.5 for a head. However, if I perform an experiment and flip a coin 100 times, tails might come up 44 times and heads 56 times.

Theoretical and experimental probabilities (video) | Khan ...
• Experimental probability is the result of an experiment, and the theoretical probability is based on the mathematical model developed on the probability theory. • The accuracy of the results of the experiments directly depends on sample size of the experiment and accuracy is greater when the sample size is greater.

Difference Between Theoretical and Experimental Probability
Theoretical probability is what we expect to happen, where experimental probability is what actually happens when we try it out. The probability is still calculated the same way, using the number of possible ways an outcome can occur divided by the total number of outcomes.

Theoretical vs. Experimental Probability
The probability of an event is a number from 0 to 1 that measures the chance that an event will occur. In this lesson, we will look into experimental probability and theoretical probability.

Difference between experimental probability and theoretical probability A coin will help us see the difference. In theoretical probability, we say that "each outcome is equally likely " without the actual experiment. For instance, without flipping a coin, you know that the outcome could either be heads or tails.
